

Does "Assets = Liabilities + Equity" hold as vector arithmetic? Two real embedding models

(a) General GloVe: identity holds
Liabilities + Equity $\approx$ Assets (cos 0.63)

```
nearest to Liab+Equity (full 400k vocab):
    assets    0.63
    debt      0.61
    investments 0.60
=> assets is the #1 nearest word
```

(b) Finance-tuned: identity breaks
sum lands among *leverage/balance*, not assets

```
nearest to Liab+Equity (balance-sheet terms):
    debt      0.88
    balance    0.87
    leverage   0.86
    assets     0.85
=> assets only rank 4
```
